APPENDIX I
RISK ASSESSMENT GUIDANCE FOR SUPERFUND
PART D, TABLES

Introduction to Appendix I tables

The tables in this appendix were developed in accordance with *Risk Assessment Guidance for Superfund: Volume I, Human Health Evaluation Manual (Part D)* (RAGS D) (EPA, 1998). The RAGS D guidance was developed by the EPA to assist in standardizing risk assessment planning, reporting, and review at Comprehensive Environmental Response Compensation and Liability Act (CERCLA) sites. The standard tables contained in this appendix were developed by the EPA to clearly and consistently document the parameters, data, and calculations used in the human health risk assessment. The results tables were standardized by EPA in order to facilitate easy entry of all risk assessment results into the EPA CERCLIS database.

The Appendix tables are numbered with the following convention: appendix letter, table number, and in parentheses, the table number corresponding to the RAGS D guidance (EPA, 1998) and the individual table number within the series. For example, Table I-85 (RAGS D, Table 7.1) is the 85th table in Appendix I and is the first in a series of tables that follow the RAGS D format for Table 7 series. The ten standard table formats used in this risk assessment are described below. Please note that multiple versions of specific tables are used to address different exposure pathways or different exposure points.

- **Table 1 (series)–Selection of Exposure Pathways** includes the exposure pathways that were selected for analysis and the exposure pathways that will be evaluated quantitatively in the risk assessment.
- **Table 2 (series)–Occurrence, Distribution, and Selection of COPCs** includes statistical information about each detected chemical (minimum and maximum value, location of maximum value, and detection frequency), the detection limits, and the toxicity screening values used for the COPC selection. Table I-2 presents the groundwater data for JPL collected from 1994 to 1998. Table I-3 presents the chemicals selected as COPCs from the first step of the screening process using the 1994-1998 data. The statistical information presented in Table I-3 is for 1997-1998 data for the selected COPCs. Both Table I-2 and I-3 compare the maximum detection of each chemical across the site to the screening toxicity value and include a column indicating if the chemical was selected as a preliminary COPC. The remaining Tables I-3 through I-40 present the well by well data for the COPCs for each JPL monitoring well and the off-site production wells. Table I-41 presents the statistical information for the lead detections in the JPL monitoring wells. The groundwater lead concentrations were used to calculate blood lead concentrations in several receptors for comparison to the level of concern toxicity value. Appendix K presents the lead methodology and the State of California model used to calculate blood lead concentrations.
- **Table 3 series–Medium-specific Exposure Point Concentration Summary** includes statistical information which was used to calculate the exposure point concentrations (EPCs) and reasonable maximum exposure (RME) and central

tendency (CT) values. For the purposes of this risk assessment, only RME exposure was considered.

- **Table 4 series–Values Used for Daily Intake Calculations** presents the input parameters, parameter definitions, units, RME value and references used in the calculation of the intake for each exposure pathway.
- **Table 5 series–Non-cancer Toxicity Data** presents the reference dose (RfD) for the oral, dermal, and inhalation pathways and includes the modifying factors, adjustment factors, the organ effects of each COPC, and references.
- **Table 6 series–Cancer Toxicity Data** includes the oral, dermal, and inhalation toxicity value for chemicals of potential concern, EPA weight of evidence descriptions, and references.
- **Tables 7 and 8 series–Calculation of Non-cancer Hazards and Cancer Risks** includes the information used in the calculation of the intake values for both noncarcinogenic and carcinogenic risks. The information includes the EPC value, the calculated intake value, the cancer slope factors, reference doses, and the calculated non-cancer hazard quotient/index and cancer risk values for each COPC.
- **Table 9 series–Risks and Hazards** presents the cancer risks and non-cancer hazard indices calculated for each potential receptor for each COPC. The cancer and noncancer risk values are presented for each exposure route and chemical. The total risk values represent the sum of the risks for all pathways combined. The noncancer hazard index also includes the HI calculated for the primary organ effected (target organ).
- **Table 10 series–Risks and Hazards** is similar to Table 9 but includes information only for those chemicals that non-cancer hazards or risks above acceptable levels.

LIST OF TABLES

- Table I-1 (RAGS Part D, TABLE 1) SELECTION OF EXPOSURE PATHWAYS Jet Propulsion Laboratory—Operable Units 1 and 3
- Table I-2 (RAGS Part D, TABLE 2.1) OCCURRENCE, DISTRIBUTION AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN Jet Propulsion Laboratory—Summary of Data for All Wells (1994-1998)
- Table I-3 (RAGS Part D, TABLE 2.2) OCCURRENCE, DISTRIBUTION AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN Jet Propulsion Laboratory—Summary of Data for All Wells (1997-1998)
- Table I-4 (RAGS Part D, TABLE 2.3) OCCURRENCE, DISTRIBUTION AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN Jet Propulsion Laboratory—Monitoring Well 01
- Table I-5 (RAGS Part D, TABLE 2.4) OCCURRENCE, DISTRIBUTION AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN Jet Propulsion Laboratory—Monitoring Well 03
- Table I-6 (RAGS Part D, TABLE 2.5) OCCURRENCE, DISTRIBUTION AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN Jet Propulsion Laboratory—Monitoring Well 04
- Table I-7 (RAGS Part D, TABLE 2.6) OCCURRENCE, DISTRIBUTION AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN Jet Propulsion Laboratory—Monitoring Well 05

- (1) Minimum/maximum detected concentration
 (2) Screening was not performed on a well-by-well basis.
 (3) Background information was not available.
 (4) Screening toxicity value derived in accordance with State of California Department of Toxic Substances Control *Preliminary Endangerment Assessment Guidance Manual (DTSC 1994)* and *EPA Region IX PRG Table (EPA 1999)*

Definitions:

ARAR/TBC = Applicable or Relevant and Appropriate Requirement/To Be Considered
 CAS = Chemical Abstract Service
 COPC = chemical of potential concern
 DTSC = Department of Toxic Substances Control
 EPA = U.S. Environmental Protection Agency
 mg/L = milligrams per liter
 MW = monitoring well
 N/A = Not applicable
 N/D = Not detected
 PRG = Preliminary Remedial Goal
 RAGS = Risk Assessment Guidance for Superfund

- (1) Minimum/maximum detected concentration
- (2) Screening was not performed on a well-by-well basis.
- (3) Background information was not available.
- (4) Screening toxicity value derived in accordance with State of California Department of Toxic Substances Control *Preliminary Endangerment Assessment Guidance Manual* (DTSC 1994) and EPA *Region IX PRG Table* (EPA 1999)

Definitions:

CAS = Chemical Abstract Service
 ARAR/TBC = Applicable or Relevant and Appropriate Requirement/To Be Considered
 COPC = Chemical of Potential Concern
 DTSC = Department of Toxic Substances Control
 EPA = U. S. Environmental Protection Agency
 N/A = Not applicable
 N/D = Not detected
 PRG = Preliminary Remedial Goal
 RAGS = Risk Assessment Guidance for Superfund
 ug/L = micrograms per liter
 VW-4 = Valley Well #4

Table I-41 (RAGS Part D, TABLE 2.40)
 OCCURRENCE, DISTRIBUTION AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN
 Jet Propulsion Laboratory—Summary of Lead Data (1997-1998) and Comparison of
 Modeled Blood Lead Concentrations to Screening Toxicity Value

Scenario Timeframe: Current/Future
 Medium: Groundwater
 Exposure Medium: Groundwater
 Exposure Point: All Wells (1997-1998)—Tap Water

(1) Minimum/maximum detected concentration

(2) Values are 99th percentile child blood lead concentrations estimated using State of California guidance (DTSC 1996) and are expressed in micrograms of lead per deciliter of blood (ug/dl). Exposure point concentrations used to estimate blood lead concentrations are presented in Appendix H along with model and input parameters.

(3) Background information was not available.

(4) Blood lead concentration of concern in children and adults is 10 ug/dl (DTSC 1996).

Definitions:

ARAR/TBC = Applicable or Relevant and Appropriate Requirement/To Be Considered

CAS = Chemical Abstract Service

COPC = chemical of potential concern

DTSC = Department of Toxic Substance Control

mg/L = milligrams per liter

MW = monitoring well

N/A = Not applicable

RAGS = Risk Assessment Guidance for Superfund

ug/dl = micrograms of lead per deciliter of lead

(1) Adjusted Inhalation RfD = RfC x (20 m3/day) / (70 kg)

(2) RfD based on route-to-route extrapolation.

(3) Value obtained from EPA Region IX PRG Summary Table (EPA 1999). Target organ and uncertainty/modifying factors are not provided.

(4) EPA Region IX PRG Summary Table expires May 1999

(5) RfD value has been withdrawn.

Definitions:

EPA = U.S. Environmental Protection Agency

kg= kilograms

m3/day = cubic meters per day

mg/kg/day = milligrams per kilogram per day

mg/m3 = milligrams per cubic meter

MM/DD/YY = month/day/year

N/A = Not applicable

NCEA = EPA's National Center for Environmental Assessment

PRG = preliminary remediation goal

RAGS = Risk Assessment Guidance for Superfund

RfC = reference concentration

RfD = reference dose

RfD _i	noncancer inhalation reference dose
RfD _o	noncancer oral reference dose

1.0 INTRODUCTION

This appendix explains the methodology used to derive screening toxicity value for use in the baseline risk assessment. Screening toxicity values were derived in accordance with the State of California Environmental Protection Agency Department of Toxic Substances Control (DTSC) *Preliminary Endangerment Assessment (PEA) Guidance Manual* (DTSC, 1994) and United States Environmental Protection Agency (EPA) *Risk Assessment Guidance for Superfund* (EPA, 1989). California PEA values and EPA PRG values are derived using similar equations and input parameters with slight modifications. The California PEA values were calculated using the residential human receptor exposure parameters listed in Table J-1. Chemical-specific toxicity values used in developing the PRGs are shown in Tables J-2 and J-3. Potential household exposure from direct ingestion, dermal contact, and inhalation of volatile organic compounds was evaluated for the residential land use scenario. The EPA PRG values were obtained directly from the Region IX PRG tables (EPA, 1999).

1.1 Toxicity Values

Toxicity values, chronic noncarcinogenic reference doses (RfDs) and carcinogenic slope factors (CSFs) were obtained from the California Office of Environmental Health Hazard Assessment (CAOEHHA) (CAOEHHA, 1994), the Integrated Risk Information System (EPA, 1998), the Health Effects Assessment Summary Tables (EPA, 1997), and the Region IX PRG tables (EPA, 1999).

When no toxicity values were available for a given route of exposure, EPA Region IX's route-to-route extrapolations were used (EPA, 1999). Oral cancer slope factors (CSF_o) and oral reference doses (RfD_o) were used for both oral and inhaled exposures for organic compounds lacking inhalation values. Inhalation cancer slope factors (CSF_i) and inhalation reference doses (RfD_i) were used for both inhaled and oral exposures for organic compounds lacking oral values. Oral toxicity values were used for evaluating dermal exposure (DTSC, 1994).

1.2 Dermal Permeability Coefficients

Chemical-specific dermal permeability coefficients (K_p) estimates for contaminants in groundwater are presented in Table J-4. When a chemical-specific K_p was not available, the K_p was estimated using a surrogate chemical with similar molecular weight and K_{ow} value (DTSC, 1994). Information used to estimate K_p s is presented in Table J-5.

1.3 Exposure Factors

Default exposure factors were obtained primarily from the PEA manual (DTSC, 1994) and from *Supplemental Guidance: Standard Default Exposure Factors* (EPA, 1991). Because contact-rates may be different for children and adults, carcinogenic risks were calculated using a time-weighted average approach which incorporates both childhood

exposure (0 to 6 years) and adult exposure (7 to 30 years). This approach approximates the integrated exposure from birth until age 30. Noncarcinogenic contaminants were evaluated for children only. It is assumed if the hazard index is not exceeded for the child, it will not be exceeded for any other age group (DTSC, 1994).

1.4 PRG Equations

The equations used to calculate the California PEA values for carcinogenic and noncarcinogenic chemicals are presented in Equations J-1 through J-4. The equations are based on DTSC equations contained in the PEA manual (DTSC, 1994). The methodology back-calculates a groundwater concentration level that corresponds to a target risk of 1.0×10^{-6} for carcinogens or a hazard quotient of 1.0 for noncarcinogens.

1.5 Determining the Appropriate PRG

California PEA values were derived using available carcinogenic and noncarcinogenic toxicity values. For example, chronic RfDs and CSFs have been developed for 1,1-dichloroethane; therefore, two screening toxicity values were derived for this chemical—one reflecting its carcinogenic toxicity and one reflecting its noncarcinogenic toxicity. The derived California PEAs are shown in Table J-6. Also shown in Table J-6 are the Region IX PRGs (EPA, 1999). The California PEA values and EPA Region IX PRGs were compared; the lower, more conservative value was used for the screening level comparison.

1.0 INTRODUCTION

This appendix explains the methodology used to assess health risks from inorganic lead (Pb) for use in the baseline human health risk assessment. Health risks from exposure to inorganic Pb were assessed based on a mathematical model provided by State of California Department of Toxic Substance Control (DTSC) guidance (DTSC, 1996).

The traditional reference dose approach to toxic chemicals is not applied to Pb because most human health effects data are based on blood Pb concentrations rather than on a dose. Therefore, site-specific blood Pb concentrations were estimated for the receptor populations, and then compared to a blood Pb concentration of concern for the protection of human health. Blood Pb concentrations in adults and children were estimated based on a multipathway analysis. Blood Pb concentrations reflect total exposure from site-related and background sources.

1.1 Exposure Pathways

This methodology estimates blood Pb concentrations resulting from exposure via diet, drinking water, soil and dust ingestion, inhalation, and dermal intake. Each pathway is represented by an equation relating an incremental blood Pb increase to a concentration in a medium, using contact rates and empirically determined ratios. The contributions via the five pathways are added to arrive at an estimate of median blood Pb concentration resulting from the multipathway exposure. The resulting estimate reflects total exposure from site-related and background sources.

1.2 Equations

The equations used in the mathematical model to estimate blood Pb concentrations are presented in Equations K-1 through K-5 and are based on DTSC equations (DTSC, 1996). The model estimates 90th, 95th, 98th, and 99th percentile concentrations from the median by assuming a lognormal distribution with a geometric standard deviation of 1.42.

The State of California guidance (DTSC, 1996) was used in conjunction with a spreadsheet obtained from DTSC. The parameters used in the spreadsheet are discussed below. Although the only potential receptors applicable to this human health risk assessment are adults and children, the equations used in the spreadsheet estimate blood Pb concentrations for adults, children, pica children, and industrial workers as micrograms of Pb per deciliter of blood ($\mu\text{g}/\text{dl}$). For completeness, blood Pb estimates are presented for all potential receptors. Outputs from the model are included as Model Outputs K-1 through K-10.

1.3 Model Parameters

Model parameters are listed in Table K-1. The distribution of blood Pb concentrations for a given set of environmental inputs is a factor in protecting sensitive members of the population. Because blood Pb concentrations are assumed to be lognormally distributed, upper-bound values for contact rates are not used, because they would distort the percentiles corresponding to blood Pb concentrations.

In the absence of applicable site-specific data, the DTSC recommended default values for the concentration of Pb in ambient air and the concentration of respirable airborne dust were assumed to be 0.18 micrograms per cubic meter ($\mu\text{g}/\text{m}^3$) and 50 $\mu\text{g}/\text{m}^3$, respectively. The concentration of Pb in soil was assumed to be equal to the mean Pb background value for

California of 23.9 milligrams per kilogram (Bradford *et al.*, 1996). The regional background level of lead was selected for use in the model because appropriate site-specific background concentrations of lead were not available. Concentrations of Pb in water are summarized in Table K-2. Refer to Section 6.1.7 of the text for the discussion regarding determining the concentration of Pb in water. The concentration of Pb in the diet was assumed to be 10 micrograms per kilogram (Bolger *et al.*, 1990).

1.4 Comparison to the Blood Lead Concentration of Concern

After blood Pb concentrations were estimated, a comparison of the estimated 99th percentile blood Pb concentration to the blood Pb concentration of concern was completed. The State of California has established a blood Pb concentration of concern for children and adults of 10 µg/dl (DTSC, 1996). The comparison is summarized in Table K-3. The results show that all the estimated blood Pb levels associated with each well are less than the 10 µg/dl level of concern.

1,1-DICHLOROETHENE

COMMON SYNONYMS: • Vinylidene chloride	CAS NUMBER: 75-35-4 FORMULA: C ₂ H ₂ Cl ₂ MOLECULAR WEIGHT: 96.94	CHEMICAL STRUCTURE 
PHYSICAL/CHEMICAL DATA	Physical State - liquid Solubility in water (mg/L) - 2,500 at 20°C K _{oc} (mL/g) - 65 Diffusivity in air (cm ² /sec) - 0.0791 Diffusivity in water (cm ² /sec) - 1.04 × 10 ⁻⁵ Henry's Law constant (atm-m ³ /mol) - 0.154 Bioconcentration factor (L/kg) - no data	EPA, 1999a EPA, 1999a EPA, 1999a EPA, 1999a EPA, 1999a EPA, 1999a
MAJOR USES	Used primarily in the production of other chlorinated hydrocarbons, plastics, refrigerants, and polymers.	EPA, 1999a ATSDR, 1996

TOXICOKINETICS

In laboratory animals, 1,1-dichloroethylene (DCE) is rapidly absorbed via inhalation. Substantial amounts of the parent compound were found in the blood of rats 2 minutes after inhalation exposure. Absorption was dose- and duration-dependent, and decreased over time until equilibrium was reached. Animal studies also show that oral exposure to 1,1-DCE results in rapid and almost complete absorption. Once absorbed, 1,1-DCE was found to distribute rapidly in the bodies of experimental animals. 1,1-DCE appears to partition preferentially in the liver, kidney, and lung tissues. Much of the absorbed 1,1-DCE is breathed out unchanged through the lungs. The bulk of the remaining chemical that is eliminated exits the body via the urine (EPA, 1999a; ATSDR, 1996).

TOXICITY

Noncarcinogenic Effects

1,1-DCE is irritating to the lungs and eyes. Acute exposure to high concentrations of 1,1-DCE may cause narcosis similar to drunkenness. Exposure to 1,1-DCE over prolonged periods may cause renal and hepatic dysfunction. Effects on the heart have also been noted. Dermal exposure to 1,1-DCE may cause irritation of the skin. Based on studies conducted in rats, mice, and rabbits, 1,1-DCE may be weakly teratogenic (EPA, 1999a; ATSDR, 1996). EPA has established an oral reference dose (RfD) for 1,1-DCE of 9×10^{-3} milligrams per kilogram body weight per day (mg/kg/day), based on hepatic lesions in a chronic rat oral bioassay (EPA, 1999b).

Carcinogenic Effects

There is inadequate evidence in humans linking exposure to 1,1-DCE and incidence of tumors. Epidemiologic data have shown no carcinogenic effect associated with 1,1-DCE exposure. The evidence for carcinogenicity in animals is also limited. Most of the 18 animal studies reported were limited in design and were not designed for maximum sensitivity. The

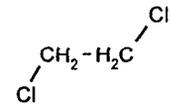

results of these studies are mixed. 1,1-DCE has been shown to be mutagenic for *Salmonella typhimurium* in multiple assays, but did not produce chromosomal aberrations in V79 cells or bone marrow cells of ICR mice treated *in vivo*. Because of the limited and varying data, The U.S. Environmental Protection Agency (EPA) has listed 1,1-DCE as a Group C possible human carcinogen.

Of the 18 studies reported, only one inhalation study showed 1,1-DCE to be a complete carcinogen. This study was performed by Maltoni *et al.* Both sexes of Swiss mice were exposed to 10 and 25 parts per million (ppm) 1,1-DCE for 4 to 5 days per week for 1 year. A statistically significant increase in kidney adenocarcinomas was noted but a dose-response relationship was not clear (EPA, 1999b). At no time has the Maltoni *et al.* data been subjected to the peer review process, which would ensure the quality of the data. In addition, the Maltoni *et al.* studies were performed at the Bologna Institute of Oncology, which has not been inspected by the EPA; therefore, the data can't have the same confidence for regulatory purposes as the data that originate in certified, inspected laboratories. The weight of evidence indicates that 1,1-DCE is not carcinogenic in experimental animals, except for the data reported by Maltoni *et al.*

Based on this single study demonstrating tumors in one mouse strain after inhalation exposure, EPA has set an oral cancer slope factor (CSF) of $6 \times 10^{-1} \text{ (mg/kg/day)}^{-1}$, and an inhalation unit risk of 5×10^{-5} per gram per cubic meter $(\text{g/m}^3)^{-1}$ (EPA, 1999b). The California Office of Environmental Health Hazard Assessment (OEHHA) has not set an inhalation or oral CSF for 1,1-DCE (OEHHA, 1994a). In summary, the cancer assessment of 1,1-DCE is uncertain for the following reasons:

- Seventeen out of 18 animal bioassays did not show 1,1-DCE to be carcinogenic.
- A dose-response relationship was not apparent in the Maltoni *et al.* study.
- The Maltoni *et al.* data on which the CSFs are based have not been peer reviewed.
- The Bologna Institute of Oncology has not been inspected by the EPA, so the claim that Maltoni *et al.* followed good laboratory practices can't be confirmed.
- OEHHA has not promulgated a CSF.

1,2-DICHLOROETHANE

COMMON SYNONYMS: <ul style="list-style-type: none"> • Ethylene dichloride 	CAS NUMBER: 107-06-2 FORMULA: C ₂ H ₄ Cl ₂ MOLECULAR WEIGHT: 98.96	CHEMICAL STRUCTURE 
PHYSICAL/CHEMICAL DATA	Physical State - oily Solubility in water (mg/L) - 8,700 at 20°C K _{oc} (mL/g) - 33 Diffusivity in air (cm ² /sec) - 0.091 Diffusivity in water (cm ² /sec) - 9.9 × 10 ⁻⁶ Henry's Law constant (atm-m ³ /mol) - 0.0012 Bioconcentration factor (L/kg) - 2.0	EPA, 1999a EPA, 1999a EPA, 1999a EPA, 1999a EPA, 1999a EPA, 1999a EPA, 1999a
MAJOR USES	Used as a solvent for fats, oils, waxes, and rubber; as a chemical intermediate for various chlorinated compounds including vinyl chloride; insecticidal properties recognized in the late 1920s when it was first used as a fumigant for stored products.	Budavari <i>et al.</i> , 1989 EPA, 1984c, 1999a Smith, 1991

TOXICOKINETICS

High absorption of 1,2-dichloroethane (DCA) has been demonstrated in laboratory animals. Absorption across the gastrointestinal tract is rapid with peak blood levels occurring within 20 minutes after a single oral dose. Since 1,2-DCA has a fairly high vapor pressure and a high blood-to-air partition coefficient, pulmonary absorption is expected to be rapid and complete (EPA, 1984c). Rats exposed absorbed about 70 percent of the 1,2-DCA inhaled (Smith, 1991). Slight absorption may occur through the skin (EPA, 1984c). 1,2-DCA is rapidly cleared from the body, with a biological half-life of less than 1 hour. Urine is the primary route of elimination. Approximately 30 percent of an oral dose will be eliminated through the lungs, whereas only 2 percent of an inhaled dose will be removed through this pathway. The metabolism of 1,2-DCA is mediated by cytochrome P450. Metabolites found in the urine are thiodiacetic acid and thiodiacetic acid sulfoxide (Smith, 1991).

TOXICITY

Noncarcinogenic Effects

Exposure to 1,2-DCA vapors in the workplace has caused anorexia, nausea, vomiting, weakness, fatigue, nervousness, and irritation of the respiratory tract and eyes. Nervous system dysfunction has also been reported in chronically exposed workers (EPA, 1984c). Rats exposed to lethal levels of 1,2-DCA died from cardiac arrest, preceded by respiratory arrest. Rats fed diets fumigated with 500 and ppm 1,2-DCA for 2 years were not affected in terms of their growth, fertility, reproduction, or biochemistry (Smith, 1991). Accidental oral exposure to 1,2-DCA in humans has resulted in gastroenteritis, followed by liver and kidney injury. Intestinal hemorrhaging was observed in some cases (Smith, 1991). Death of one individual occurred following a single oral exposure of 0.5-1.0 grams per kilogram (g/kg) of

1,2-DCA. The autopsy revealed liver necrosis and focal adrenal degeneration and necrosis (EPA, 1999a). No inhalation or oral reference doses have been set by the EPA due to a lack of data (EPA, 1999b).

Carcinogenic Effects

1,2-DCA does bind covalently to deoxyribonucleic acid (DNA) and other cellular macromolecules. It has been found to be only weakly mutagenic in the Ames mutagenicity assay, but its metabolites are more positively mutagenic. Chronic bioassays in rodents have been positive for carcinogenicity by the oral but not the inhalation route. Chronic, oral exposures to the maximum tolerated doses (MTD) have produced an increased incidence of alveolar and bronchiolar adenomas in both sexes; hepatocellular carcinomas in males; and mammary adenocarcinomas, endometrial tumors, and squamous cell carcinomas in females. Similar tumors were not observed in mice or rats exposed via inhalation to the MTD. Pathological examinations revealed damage to tissues including necrosis of the liver and tubular and glomerular degeneration of the kidney (Smith, 1991). Some epidemiological studies have shown a positive association between exposure to 1,2-DCA and cancer, while others have not (Smith, 1991).

EPA has placed 1,2-DCA in Group B2, indicating that it is a probable human carcinogen based on positive findings in chronic bioassays in which rats were exposed orally. The inhalation unit risk is 2.6×10^{-5} per microgram per cubic meter $[(\text{mg}/\text{m}^3)^{-1}]$ for inhalation. The CSFs are $0.091 (\text{mg}/\text{kg}/\text{day})^{-1}$ for both inhalation and oral exposure (EPA, 1999b). The California OEHHA has set both oral and inhalation CSFs of $7.0 \times 10^{-2} (\text{mg}/\text{kg}/\text{day})^{-1}$ (OEHHA, 1994b).

ARSENIC

COMMON SYNONYMS:	CAS NUMBER: 7440-38-2 FORMULA: As MOLECULAR WEIGHT: 74.92	
PHYSICAL/CHEMICAL DATA	Physical State - metal (crystalline solid) Density - 5.727 at 14°C Solubility in water (mg/L) - insoluble K _{oc} (mL/g) - NA Diffusivity in air (cm ² /sec) - NA Diffusivity in water (cm ² /sec) - NA Henry's Law constant (atm-m ³ /mol) - NA Bioconcentration factor (L/kg) - 4	EPA, 1999a EPA, 1999a EPA, 1999a ATSDR, 1993a
MAJOR USES	Used in arsenical pesticides; metallurgy for making alloys of copper or lead; making various types of glass.	EPA, 1999a

INTRODUCTION

Arsenic occurs naturally in air, water, soil, plant, and in the tissues of living organisms. Occurrence of arsenic in the environment can be a result of industrial and agricultural activities. Arsenate (As⁺⁵) is the main species of arsenic found in environments such as unflooded soils. Mildly reducing conditions favor the arsenite (As⁺³) form (Goyer, 1991; EPA, 1999a; Lewis, 1992).

TOXICOKINETICS

Studies of tri- and pentavalent arsenic indicate almost complete absorption through the gastrointestinal tract in most laboratory animals and humans. Inhalation and absorption of arsenic is dependent upon the size of the particle inhaled. Large particles are quickly deposited in the upper airways and removed by ciliary action; therefore, there is only limited absorption across lung tissue. Small particles penetrate deep into the lungs into the alveoli and, dependent upon the chemical form of the arsenic, absorption across alveolar epithelium occurs. Data also indicate soluble forms (e.g., tri- and pentavalent arsenic) are rapidly absorbed through the skin (EPA, 1999a; ATSDR, 1993a).

Once absorbed, all but a small fraction of systemic arsenic is cleared from tissues. Arsenic seems to distribute preferentially in the nails, skin and hair. There is also general agreement that arsenic will initially accumulate in the kidney, liver, bile, brain, skeleton, and blood (ATSDR, 1993a).

Most of the absorbed arsenic is quickly cleared from tissue. The major metabolite is dimethylarsenate, which is found in the urine. Monomethylarsenate is often a secondary metabolite, and can also appear in the urine. Arsenic is also known to be eliminated through the skin in sweat, particularly during periods of profuse sweating (Goyer, 1991).

TOXICITY

Noncarcinogenic Effects

Oral exposures of humans to arsenic can produce a large range of gastrointestinal disturbances, including nausea, vomiting, diarrhea, and thirst. Anemia, cardiovascular effects, seizures, and toxic delirium have also been noted. Inhalation exposures can cause all of the above, including pulmonary edema. Skin exposures have commonly caused hyperpigmentation, keratosis, epidermoid carcinomas, and occasionally skin sensitization (EPA 1999a; ATSDR, 1993a; Goyer, 1991).

A no observable adverse effect level (NOAEL) of 0.009 mg/L was established by the EPA, based on hyperpigmentation, keratosis and possible vascular complications. An oral RfD of 3×10^{-4} mg/kg/day was also established by the EPA based on these effects (EPA, 1999b).

Carcinogenic Effects

Arsenic is a confirmed teratogen that can traverse placental barriers and cause fetal death and malformations in many species of mammals (EPA, 1999a; Goyer, 1991). It is carcinogenic in humans, and is classified by EPA as a Group A carcinogen. EPA has established an inhalation unit risk of 4.3×10^{-3} (mg/m³)⁻¹ and an oral CSF of 1.5 mg/kg/day⁻¹. The California OEHHA has set an inhalation CSFs of 12 (mg/kg/day)⁻¹ (OEHHA, 1994b). OEHHA has not established an oral CSF for arsenic.

BROMODICHLOROMETHANE

INTRODUCTION

Bromodichloromethane (BDCM), is a low-molecular-weight halogenated hydrocarbon and a trihalomethane (others being chloroform, dibromochloromethane, and bromoform). The trihalomethanes are produced during use of chlorination for water purification and result from interaction with naturally occurring humic substances in the raw water. Raw water with lower turbidity has generally been found to yield treated water that is low in the trihalomethanes (Casarett and Doull, 1986).

TOXICOKINETICS

As with the other trihalomethanes, BDCM can be absorbed through the lungs, gastrointestinal, and to a limited extent, through the skin. Humans are primarily exposed via inhalation. Once absorbed, BDCM is distributed to all organs with relatively high concentrations accumulating in nervous and adipose tissues. The majority of an absorbed dose is excreted unchanged by the lungs or as the carbon dioxide metabolite. BDCM can cross the placenta rapidly and enter fetal circulation. (EPA, 1995)

TOXICITY

Noncarcinogenic Effects

An oral RfD of .02 mg/kg/day was established by EPA, based on a lowest observable adverse effect level (LOAEL) of 17.9 mg/kg/day from a chronic rat and mouse gavage assay (EPA, 1995). In this assay, final mean body weights of dosed female and male mice were 75 to 91 percent that of control mice. Changes observed in dosed specimens included cytomegaly and tubular cell hyperplasia of the kidney, fatty metamorphosis of the liver, clear cell change, focal cellular change, and eosinophilic cytoplasmic change. In another subchronic bioassay, degeneration of the liver, degeneration and necrosis of the kidney, and kidney and liver lesions were observed in rats and mice administered varying doses of BDCM orally. The data from the study defined a NOAEL of 35.7 mg/kg/day, above which male mice experienced kidney lesions and depressed body weight. However, greater confidence is placed in the LOAEL. Overall confidence in the EPA RfD is rated medium to low (EPA, 1995).

Carcinogenic Effects

EPA classifies BDCM as a Group B2 probable human carcinogen, based on inadequate human data and sufficient evidence of carcinogenicity in rats and mice, as shown by increased incidence of kidney tumors and tumors of the large intestine in male and female rats, kidney tumors in male mice, and liver tumors in female mice (EPA, 1995; National

Toxicology Program [NTP], 1987). Several ecological and case-control studies have indicated a positive correlation between drinking chlorinated water and the incidence of several human cancers; in particular, bladder, rectal, and colon cancer. However, the contribution of BDCM to these carcinogenic effects cannot be distinguished from the possible contributions of the other trihalomethanes. Based on the available animal data, EPA has developed an oral CSF of 0.062 mg/kg/day (EPA, 1995). The California OEHHA has established an oral and inhalation CSF of $0.13 \text{ (mg/kg/day)}^{-1}$ (OEHHA, 1994b).

CARBON TETRACHLORIDE

Introduction

Carbon tetrachloride (CCl₄) is a clear liquid with a sweet odor resembling chloroform. Major uses of carbon tetrachloride include as a solvent, as a cleaning agent for machinery and electrical equipment, as a catalyst, and in the synthesis of other chemicals, such as freons (EPA, 1996b). It was previously used as a fumigant to kill insects in grain (ATSDR, 1994).

Toxicokinetics

Carbon tetrachloride is readily absorbed through the lungs, gastrointestinal (GI) tract, and skin. It is distributed to all organs and tissues, but concentrates in body fat, liver, and bone marrow. Absorption through the lungs decreases as duration increases until an equilibrium is reached. Absorption through the GI tract is greatly affected by diet. Carbon tetrachloride in air is predominantly expired unchanged. Some is metabolized in the liver to chloroform or carbon dioxide. An intermediate compound in the metabolic pathway, trichloromethyl radical, can irreversibly bind hepatic macromolecules and may be responsible for lipid peroxidation, a process that causes damage to membranes and enzymes (EPA, 1996a; Andrews and Snyder, 1991).

TOXICITY

Noncarcinogenic Effects

Prolonged skin exposure to carbon tetrachloride can cause irritation. Effects following acute exposure to high levels may be delayed and may include damage to the heart, liver, and kidneys. Kidney damage is more likely after inhalation exposure, whereas liver damage is more likely after oral exposure. Carbon tetrachloride vapor may act as a central nervous system depressant (EPA, 1996b). The mechanism of action for toxicity in the liver is centrilobular necrosis and fat accumulation. Metabolites of carbon tetrachloride are considered to be responsible for its toxic action in the liver.

EPA has established an oral RfD for carbon tetrachloride of 7×10^{-4} mg/kg/day. The basis for the RfD is a study in which rats administered carbon tetrachloride by gavage developed liver lesions. In extrapolating from the study results to a human toxicity criteria, an uncertainty factor of 1,000 was applied the toxicity data from the study (EPA, 1996b). Compared to the oral RfDs for other common chlorinated volatile organic compounds (VOCs) such as perchloroethylene (0.01 mg/kg/day), and 1,1-dichloroethane (0.1 mg/kg/day), carbon tetrachloride (RfD equal to 0.0007 mg/kg/day) is clearly a highly toxic VOC. (A lower RfD indicates a more toxic compound.) EPA has not established an inhalation RfD due to a lack of data. However, EPA's Environmental Criteria and Assessment Office (ECAO) has established a provisional inhalation RfD of 5.7×10^{-4}

mg/kg/day. This RfD has not been formally reviewed by EPA and it is not considered promulgated until EPA enters it into its Integrated Risk Information System (IRIS) database.

Carcinogenic Effects

Cases of liver tumors in people who had been exposed to carbon tetrachloride have been reported. Oral exposure of laboratory animals including hamsters, rats, and mice, to carbon tetrachloride has resulted in the formation of liver cell carcinomas. No studies regarding the carcinogenicity of carbon tetrachloride following inhalation were located; however, because it has caused cancer via other exposure routes (*i.e.*, oral, parenteral), EPA has extrapolated oral dose-response data to inhalation data (EPA, 1996a; ATSDR, 1994).

EPA has classified carbon tetrachloride as a Group B2 carcinogen - probable human carcinogen - based on inadequate data in humans and sufficient data in animals. An oral CSF of $0.13 \text{ (mg/kg/day)}^{-1}$ has been developed for carbon tetrachloride based on liver tumors incidence in exposed hamsters, mice, and rats. An inhalation CSF of $0.053 \text{ (mg/kg/day)}^{-1}$ was extrapolated from the oral cancer studies. An inhalation unit risk of 1.5×10^{-5} per micrograms per cubic meter ($\mu\text{g/m}^3$)⁻¹ was established by EPA (1996b). OEHHA (1994a) has established both oral and inhalation cancer slope factors of $0.15 \text{ (mg/kg/day)}^{-1}$.

CHLOROFORM

INTRODUCTION

Chloroform is trichloromethane, a volatile but nonflammable liquid with a characteristic odor. Its solubility in water is low (0.822 milliliters per 100 milliliters at 20°C) and it is miscible with organic liquids such as alcohol, benzene, ether, and carbon disulfide. It has been used as an anesthetic and in pharmaceutical preparations. It is also used as a solvent for fats, oils, rubber, alkaloids, waxes, and resins, as a cleaning agent, and as an insecticidal fumigant. The U.S. Food and Drug Administration (FDA) banned the use of chloroform in drug, cosmetic, and food packaging products in 1976. Use as an anesthetic has been discouraged since the early 1900s (Andrews and Snyder, 1991; Budavari *et al.*, 1989; EPA, 1996a).

TOXICOKINETICS

Chloroform can be absorbed through the lungs (77 to 94 percent), gastrointestinal tract (approximately 100 percent), and to a limited extent, through the skin. Humans are primarily exposed via inhalation. Once absorbed, chloroform is distributed to all organs with relatively high concentrations accumulating in nervous and adipose tissues. Sixty-eight percent of an absorbed dose is excreted unchanged by the lungs or as the carbon dioxide metabolite. The biological half-life of chloroform in the blood and expired air of humans is 1.5 hours. Chloroform can cross the placenta rapidly and enter fetal circulation (EPA, 1996a).

TOXICITY

Noncarcinogenic Effects

Due to the former use of chloroform as an anesthetic, there is a great deal of information on the effects on humans. Levels of 400 ppm are tolerable without complaint for 30 minutes. Levels of 100 ppm for 7 minutes can cause dizziness and gastrointestinal distress. Narcosis is achieved at 14,000 ppm. The central nervous system is the primary target organ for chloroform toxicity.

Chloroform toxicity is dependent on its metabolism to a reactive metabolite (possibly phosgene) which binds the proteins in the liver and deplete the organ of glutathione (Andrews and Snyder, 1991). Phosgene may also be the proximal toxicant for nephrotoxicity (Hewitt, 1991). Hepatocyte death, which accompanies chloroform toxicity, results in the influx of calcium ions into the cell, initiating a series of cytotoxic events (Plaa, 1991).

Liver and kidney damage and cardiac arrhythmias may occur following exposure to very high levels. It has been postulated that hepatotoxicity and nephrotoxicity occur independently because they are related to metabolic processes unique to each organ. Liver damage induced by chloroform has been well documented in experimental animal models. Both male and female rodents display hepatotoxicity but only males display nephrotoxicity. Sex dependent nephrotoxicity was attributed to a reactive metabolite formed by a male-specific cytochrome P-450 (Andrews and Snyder, 1991; Plaa, 1991).

Liver failure in humans is a potential side effect of chloroform-induced anesthesia. Patients experienced nausea and vomiting followed by jaundice and coma. Autopsies revealed centrilobular necrosis extending into the periportal regions. Necrotic tissues contained cells which were ballooned and had abnormally high fat concentrations. Workers exposed to chloroform complained of depression and gastrointestinal distress, but liver function tests did not indicate liver damage (Andrews and Snyder, 1991).

A chronic oral RfD of 0.01 mg/kg/day has been set for chloroform. A chronic inhalation reference concentration (RfC) does not exist at this time (EPA, 1996b).

Carcinogenic Effects

Chloroform may be embryotoxic at sufficient doses, but it does not appear to be teratogenic or mutagenic, as it produced negative results in the Ames mutagenicity assay with and without metabolic activation. Male rats developed renal epithelial cell tumors and mice developed liver tumors following oral administration of chloroform in a chronic bioassay. Carcinogenic Effects bioassays revealed that carcinogenic doses produced severe necrosis at sites where tumors developed. Noncarcinogenic doses failed to produce the same response (EPA, 1996b).

The EPA has classified chloroform as a Group B2 carcinogen based on positive results of several carcinogenicity bioassays in rodents. The inhalation unit risk is $2.3 \times 10^{-5} \text{ (mg/m}^3\text{)}^{-1}$. The oral CSF is $6.1 \times 10^{-3} \text{ (mg/kg/day)}^{-1}$ and the inhalation CSF is $8.1 \times 10^{-2} \text{ (mg/kg/day)}^{-1}$ (EPA, 1996b). OEHHA has established an inhalation and oral CSFs of $1.9 \times 10^{-2} \text{ (mg/kg/day)}^{-1}$ and $3.1 \times 10^{-2} \text{ (mg/kg/day)}^{-1}$, respectively (OEHHA, 1994a).

CHROMIUM

COMMON SYNONYMS:	CAS NUMBER: 7440-47-3 FORMULA: Cr MOLECULAR WEIGHT: 51.996	
PHYSICAL/CHEMICAL DATA	Physical State – Solid Solubility in water (mg/L) - Insoluble K _{oc} (mL/g) - no data Diffusivity in air (cm ² /sec) - no data Difusivity in water (cm ² /sec) - no data Henry's Law constant (atm-m ³ /mol) - no data Bioconcentration factor (L/kg) - 1 × 10 ⁶	EPA, 1999a EPA, 1999a EPA, 1999a
MAJOR USES	It is commonly used in the manufacture of chrome steel or chrome-nickel steel, and for plating of other metals.	ATSDR, 1993

TOXICOKINETICS

Absorption via the GI tract is relatively low, and is dependent on the water solubility of the compound and the GI transit time. Absorption following inhalation exposure is influenced by the particle size of the aerosols, as smaller sizes are able to penetrate more readily to the pulmonary regions of the respiratory tract. Chromium has been identified in the urine and blood serum of humans following occupational exposure to chromium, indicating that it is absorbed via inhalation exposure. No data was found to indicate the rate of absorption. Chromium is expected to be absorbed slowly because it can bind to extracellular macromolecules (ATSDR, 1993b).

Chromium is distributed equally among human tissues with the exception of the lung, which may contain 2-3 times the concentration of other tissues. Chromium is normally excreted through the kidneys and urine, with this route accounting for approximately 80% of absorbed chromium. Other routes of excretion include the bile and feces, milk, sweat, hair, and nails (EPA, 1999a).

TOXICITY

Noncarcinogenic Effects

Although much of the available toxicity data for chromium is for hexavalent chromium, limited data on the toxicity of trivalent chromium is available. Inhalation of trivalent chromium compounds results in depression of some indices of immune system function, including the reduction in viability of rabbit macrophages at concentrations greater than 52 ppm. Data from other studies indicate that trivalent chromium can complex with proteins and amino acids to cause allergic reactions and potentially sensitization. Parenteral administration of trivalent chromium has resulted in adverse developmental and reproductive effects in experimental animals. Chronic oral studies of chromium compounds

have not identified any adverse effects on toxicological endpoints including body and organ weights, histological appearance of tissues or on clinical chemistry values.

The EPA has established an oral reference dose of 1.0 mg/kg/day, based on a NOAEL of approximately 1,468 mg/kg/day in a feeding study in rats. An uncertainty factor of 100 and a modifying factor of 10 were applied to the NOAEL in the RfD derivation. The confidence in the RfD is low (EPA, 1999b). The federal inhalation RfD is currently under review by a EPA work group.

Carcinogenic Effects

In vivo assays for genotoxicity have demonstrated negative results for chromosome effects in non-human systems. Similarly, *in vitro* assays for gene mutations, chromosome effects and cell transformation have given negative results for trivalent chromium.

LEAD

COMMON SYNONYMS:	CAS NUMBER: 7439-92-1 FORMULA: Pb MOLECULAR WEIGHT: 207.2	
PHYSICAL/CHEMICAL DATA	Physical State - metal (solid) Density - 11.34 at 20°C Solubility in water (mg/L) - insoluble K _{oc} (mL/g) - NA Diffusivity in air (cm ² /sec) - NA Difusivity in water (cm ² /sec) - NA Henry's Law constant (atm-m ³ /mol) - NA Bioconcentration factor (L/kg) - 42	EPA, 1999 EPA, 1999 EPA, 1999 ATSDR, 1993c
MAJOR USES	Used in the past extensively as an additive to gasoline and in paint; used primarily in the production of storage batteries, oxides, chemicals, ammunition, and various metal products; in recent years, the use of lead in ceramic glazes, gasoline, solder, and in paints has declined in the U.S. in response to the adverse health effects known to be the result of lead exposure.	EPA, 1999 ATSDR, 1993c

TOXICOKINETICS

Gastrointestinal absorption of lead from consumption of food and beverages containing lead, and ingestion of soil with measurable lead levels, is the primary route of exposure. Inhaled lead deposited in the upper respiratory tract and subsequently swallowed also contributes to gastrointestinal absorption (EPA, 1986). Inorganic lead is not readily absorbed through the skin.

Once absorbed, the distribution of lead throughout the body is initially dependent on the blood level concentration and the rate of delivery to the various organs and tissues. Redistribution then occurs based on the relative affinity of the tissues for lead. The exact nature of the overall distribution and body burden are age-related. Mineralized tissues (bone) make up the largest pool for absorbed lead, accounting for approximately 95% of the total body burden in adults. Lead is also distributed in soft tissues, primarily the blood, liver, and kidneys, with lesser amounts in other tissues such as the brain, and readily passes through the placenta and distributes to fetal tissues. As a result, maternal exposure to lead can influence the overall lead body burden in infants and small children (EPA, 1990).

Inorganic lead is not metabolized in the body, but is absorbed, distributed and excreted in its original form. Lead that is absorbed from all routes is eliminated via biliary secretion and in the urine. Approximately 50-60% of absorbed lead is excreted with a half-life of 30-50 days (Kehoe, 1961; Rabinowitz *et al.*, 1976; Chamberlain *et al.*, 1978).

TOXICITY

Noncarcinogenic Effects

Extensive information regarding the health effects of exposure to lead is available. There is convincing evidence that lead exposure resulting in blood lead levels greater than 30 micrograms per deciliter ($\mu\text{g}/\text{dL}$) results in toxic effects on the peripheral and central nervous systems, the cardiovascular system, and the kidneys. In addition, evidence now suggests that children and infants are more susceptible than adults to lead toxicity, and that deleterious effects may be caused by blood lead levels upwards of 10 - 15 $\mu\text{g}/\text{dL}$. In addition, children frequently exhibit behavioral patterns that facilitate the intake of environmental lead (*e.g.*, pica).

In adults and children, severe lead toxicity is characterized by symptoms of irritability, short attention span and loss of memory, headaches, muscle tremor, peripheral neuropathy, abdominal pain, and hallucinations. In adults, these symptoms may occur at blood lead levels in the range of 40-60 $\mu\text{g}/\text{dL}$ (EPA, 1986, 1990). Non-overt symptoms of lead toxicity include decreased nerve conduction velocity and impaired cognitive function, and impaired psychomotor performance at blood lead levels upwards of 30 $\mu\text{g}/\text{dL}$. Children appear to be more sensitive than adults to the effects of blood lead levels, and the EPA has concluded that severe psychomotor and cognitive deficits appear to be associated with blood lead levels in the range of 40-60 $\mu\text{g}/\text{dL}$ (EPA, 1986, 1990). More subtle effects on mental development and cognitive ability in children are associated with blood lead levels $\leq 10-15$ $\mu\text{g}/\text{dL}$ (EPA 1990). Recent studies with primates have shown that exposure to low levels of lead can disrupt the normal maturation of the nervous system, which may result in subsequent functional deficits (Cookman *et al.*, 1987, 1988).

Blood lead levels $\geq 10-15$ $\mu\text{g}/\text{dL}$ have been associated with effects on heme metabolism, mental development of infants and children, and serum vitamin D levels. EPA (1990) has concluded that the weight-of-evidence suggests that blood lead levels in this range or possibly even lower are likely to be associated with one or more undesirable effects. At levels >30 $\mu\text{g}/\text{dL}$, nephrotoxicity and overt neurological effects are likely to occur. Reference doses for lead have not been established by EPA because lead is not considered to exhibit a threshold below which no adverse effects are expected. Instead, the EPA and the California Department of Toxic Substances Control (DTSC) have adopted a blood lead level which is considered "acceptable" based on the above data. Currently, this level is 10 $\mu\text{g}/\text{dL}$ (personal communication, Dr. Jim Carlisle, DTSC, Office of Scientific Affairs, 1993).

Carcinogenic Effects

Lead has consistently tested negative for mutagenicity in microbial systems, although the EPA has concluded that these systems are not sufficiently developed to demonstrate mutagenicity for metals that are known carcinogens. There is some evidence that lead has an effect on chromosomes in human and other mammalian species. The EPA has concluded that lead is clearly carcinogenic in animals, but that the data is insufficient for quantitative

assessment. Epidemiological data at present does not allow for an assessment of the carcinogenicity of lead in humans (ATSDR, 1993c).

NITRATE

INTRODUCTION

Nitrates arise from a number of environmental and industrial sources including fertilizers, nitrogen concentrating plants, and various organic nitrate drugs. It is also a normal component of the human diet. A typical daily intake by an adult in the United States is about 75 mg/kg-day. Of this, over 85 percent comes from the natural nitrate content of vegetables such as beets, celery, lettuce, and spinach. The contribution from drinking water is usually about 2 to 3 percent of the total (National Academy of Sciences [NAS], 1981).

TOXICOKINETICS

Nitrate toxicity is due primarily to its conversion to nitrite, which oxidizes the Fe (+2) form of iron in hemoglobin to the F3 (+3) state. This compound (methemoglobin) does not bind oxygen, resulting in reduced oxygen transport from lungs to tissues. Low levels of methemoglobin occur in normal individuals, with typical values usually ranging from 0.5 to 2.0 percent (NAS, 1981). However, due to the large excess capacity of blood to carry oxygen, levels of methemoglobin up to around 10 percent are not associated with any significant clinical signs (Walton, 1951; European Chemical Industry Ecology and Toxicology Center [ECETOC], 1988). Concentrations above 10 percent may cause a bluish color to skin and lips, while values above 25 percent lead to weakness, rapid pulse and tachypnea (Jones et al., 1973). Death may occur if methemoglobin values exceed 50 to 60 percent.

Conversion of nitrate to nitrite is mostly mediated by bacteria in the gastrointestinal system. Consequently, the risk of methemoglobinemia from ingestion of nitrate depends not only on the dose of nitrate, but also on the number and type of enteric bacteria. In healthy adults, available data suggest about 5 percent of a dose of nitrate is reduced to nitrite by bacteria in the mouth (NAS, 1981). Conversion of nitrate to nitrite may also occur in the stomach if the pH of the gastric fluid is sufficiently high (about pH 5) to permit bacterial growth. This is of concern in adults with diseases such as achlorhydria or atrophic gastritis and in infants.

TOXICITY

Noncarcinogenic Effects

Common findings associated with nitrate poisoning include unconsciousness, dizziness, fatigue, shortness of breath, nausea, vomiting, hypotension, and headache. An association between drinking nitrate-contaminated groundwater and congenital anomalies (especially neural tube defects) has been suggested by Dorsch et al., 1984 and Scragg et al., 1982. Arbuckle et al. (1988) studied water nitrates and the incidence of CNS defects in human infants. Nitrate levels of 26 ppm were associated with a moderate, but not statistically significant increase in the risk of CNS effects.

Carcinogenic Effects

An increased incidence of stomach cancer has been observed in one group of workers with occupational exposure to nitrate fertilizer. A group of 1756 male workers at a nitrate fertilizer plant experienced a slight increase in stomach cancer incidence; no increased risk of total cancers was seen (Zandjani et al., 1994). At the time of this review, no data were available to assess the mutagenic or genotoxic potential of nitrate (Micromedex, 1999).

PERCHLORATE

INTRODUCTION

Perchlorate is an oxidizing anion that originates as a contaminant in ground and surface waters from the dissolution of ammonium, potassium, magnesium, or sodium salts. Perchlorate is exceedingly mobile in aqueous systems and can persist for many decades under typical ground and surface water conditions. Ammonium perchlorate is manufactured for use in rockets, missiles, and fireworks (Rogers, 1998). Perchlorate salts are used as a component of air bay inflators, in nuclear reactors and electronic tubes, in lubricating oils, in tanning and finishing leather, in electroplating, in aluminum refining, and in the production of paints and enamels (Siddiqui et al., 1998).

TOXICOKINETICS

Perchlorate is readily absorbed from the intestinal tract, and oral uptake is considered to be the major route of exposure. Perchlorate does not pass readily through the skin (Schueplein and Bronaugh, 1983). Exposure via inhalation is expected to be negligible because the vapor pressure of perchlorate salts and acids is expected to be low at room temperatures.

Perchlorate is known to inhibit the uptake of iodide in the thyroid, causing a reduction in the hormones thyroxine and triiodothyronine (Cavalieri, 1997). Potential effects of perchlorate, given its mode of action, include concerns for carcinogenic, neurodevelopmental, developmental, reproductive, and immunotoxic effects.

TOXICITY

The EPA has established a provisional oral RfD of 0.0005 mg/kg/day for perchlorate (Stralka, 1992). This RfD is based on a study performed on 12 patients diagnosed with Graves' disease. A dose of 10 mg resulted in only partial thyroid iodine reduction. EPA considered this dosage to be a no-effect-level, which, when normalized to body weight using a standard EPA body weight of 70 kilograms, corresponds to a NOAEL of 0.15 mg/kg/day. EPA further applied an uncertainty factor of 300 (10 for acute to chronic study duration extrapolation, 10 for the protections of sensitive subpopulations, and 3 to account for database deficiencies). Applying these factors results in an oral RfD ranging from 0.0005 to 0.0001 mg/kg/d, implying that a perchlorate intake as high as 0.0005 mg/kg/day would not result in adverse health effects.

An external peer review of an analogous RfD derivation was the determination that the health effects and toxicity data were insufficient for a credible quantitative risk analysis (Toxicology Excellence for Risk Assessment, 1998a). The external peer review panel concluded that the limited database was insufficient to rule out effects of perchlorate on other organs, so it could not be determined unequivocally that the effect on the thyroid was the critical effect. In particular, the reviewers were concerned that developmental toxicity, notably neurological development affected by hypothyroidism during pregnancy, could be a

critical effect of perchlorate that had not been examined adequately in studies to date. In response to the March 1997 external peer review of the provisional RfD values, a subsequent external peer review of experts was convened in May 1997 to recommend and prioritize a set of studies to address the key data gaps and reduce uncertainties in various extrapolations (Toxicology Excellence for Risk Assessment, 1998b). The objective of the new studies is to provide a comprehensive database that provides for development of a robust RfD estimate that reduces the uncertainties inherent in the provisional values. It is anticipated that the new RfD will also be protective of subsequent cancer development.

TRICHLOROETHENE

INTRODUCTION

Trichloroethene (TCE) is widely used as an industrial solvent and is primarily used for vapor degreasing and cold-cleaning of fabricated metal parts. It is also used in textile cleaning and solvent extraction processes. Of the total TCE produced in the United States in 1982, 66 percent was used in vapor degreasing, 22 percent for export, 7 percent as chemical intermediates (in chlorinated hydrocarbons and polyvinyl chloride), and 5 percent for miscellaneous uses. TCE is not known to occur naturally in the environment. By far the greatest source of environmental release is vapor degreasing operations, which eventually release most of the TCE used in this application to the atmosphere. Sources in groundwater have included leaching from waste disposal landfills, and leakage from underground storage tanks or conveyance pipes (Bogen, 1988; EPA, 1984b, 1996a; Torkelson and Rowe, 1981).

TOXICOKINETICS

Inhaled TCE is initially taken up by the lungs at a high rate. Retention of TCE has been measured at between 37 and 75 percent of the amount inhaled regardless of the TCE concentration in the air. In animal studies, however, exposure to higher concentrations of TCE (*i.e.*, 600 ppm) results in metabolic saturation. Absorption of TCE in humans and animals following oral exposure is rapid and extensive. In animals, absorption from the gastrointestinal tract has been measured at 91 to 98 percent. Peak TCE blood levels are attained within a few hours. Absorption of TCE in animals and humans via the dermal route is poor, but dermal absorption studies are complicated by the fact that pure liquid TCE has the capability of defatting the skin, thereby enhancing its own absorption. The general conclusion has been made that normal industrial use of TCE would rarely be absorbed through the human skin in toxic amounts (ATSDR, 1988; Bogen, 1988; EPA, 1996a).

Following absorption into the body, TCE is distributed mostly into adipose tissue and highly perfused tissues such as liver and kidneys. TCE is relatively insoluble in body fluids and tends to accumulate in fatty tissues. It is capable of distributing widely throughout the body and into the fetus. Evidence from both animals and humans indicates TCE is metabolized primarily in the liver, to a wide variety of metabolites, some of which are reactive intermediates (*i.e.*, more toxic than TCE). The major metabolites of TCE are the same in humans and animals; however, metabolism in animals is much more efficient than in humans.

The mode of elimination for TCE is dose-dependent; at high levels of exposure, a larger percentage of TCE is excreted unchanged in expired air. At low levels of exposure, a greater percentage of the dose is excreted in the urine as water soluble metabolites. TCE concentrated in the adipose tissue has a long half-life, on the order of 1.75 and 2.25 hours, based on oral exposures of rats and mice (ATSDR, 1988b; Bogen, 1988; EPA, 1996a).

TOXICITY

Noncarcinogenic Effects

There is very little toxicological data for humans. Acute inhalation exposure results in mucous membrane irritation, drowsiness, and headaches. In humans, longer-term exposure (3.75 years average duration) at relatively high air concentrations (mean concentration of 85 ppm) has resulted in vertigo, headache, short-term memory loss, and decreased word association. All effects were reversed once exposure was discontinued. No other effects in humans have been definitively linked to TCE exposure. Following inhalation exposure in animals, the most sensitive target organs/systems affected vary depending on whether the exposure duration is acute, subchronic, or chronic. Short-term exposure tends to adversely impact the blood, nervous system, and reproductive system; whereas, longer-term exposure affects the liver and kidneys. Whether acute or chronic, however, the LOAEL tends to be about 100 ppm in air (ATSDR, 1988b; Bogen, 1988; EPA, 1996a).

The most sensitive organ/system impacted by oral exposure in animals is the immune system. At much greater exposure, liver, kidney and blood effects are reported. Information was not available on the oral or dermal toxicity of TCE to humans. In rabbits, the dermal lethal dose for 50 percent of the population (LD₅₀) is greater than 20 milliliters per kilogram (mL/kg), or 29 g/kg (ATSDR, 1988b; Bogen, 1988; EPA, 1996a).

Inhalation and oral studies in rodents indicate that TCE is fetotoxic, but there is no evidence that it is teratogenic. For example, skeletal ossification anomalies and other effects indicative of delayed development were reported following inhalation exposure. In a two-generation rat study (TCE in diet), liver and kidney enlargement occurred in the offspring. Other reproductive effects have been reported (e.g., mating behavior), but only at levels of exposure greater than 75 milligrams per kilogram (mg/kg). No definitive developmental or reproductive toxic effects have been reported in humans. Increased incidence of miscarriages among nurses exposed to chemicals in operating rooms and developmental effects in humans that consumed contaminated drinking water have been suggested as attributable to TCE, but in all cases, exposure has been to a multiplicity of chemicals (ATSDR, 1988b; Bogen, 1988; EPA, 1996a).

EPA has withdrawn all noncarcinogenic toxicity criteria for TCE from its IRIS database. An oral RfD of 7.35×10^{-3} mg/kg/day for TCE was located in the EPA's *Hazard Assessment for Trichloroethylene* (EPA, 1985).

Carcinogenic Effects

Available evidence indicates that TCE is carcinogenic in animals. Inhalation and oral exposure produced liver and lung tumors in mice and kidney adenocarcinoma at 600 ppm, and testicular Leydig cell tumors and possibly leukemia at concentrations greater than 100 ppm in rats. TCE did not serve as either an initiator or as a complete skin carcinogen in animal bioassays (ATSDR, 1988b; EPA, 1996b).

The mechanism of action of TCE carcinogenesis in laboratory rodents is believed to be chronic oxidative stress, caused by peroxisome proliferation in the liver. Peroxisome proliferation appears to occur at high TCE doses and is more apparent in mice than in rats. It has been argued that peroxisome proliferation does not occur in humans to an appreciable degree; therefore, rodents may not be suitable test animals for human toxicity assessment (Stott, 1988). In addition, the carcinogenic toxicity criteria is based on liver tumors in a strain of mice (B6C3F1) that is sensitive to hepatocarcinogenesis and has a high rate of spontaneous tumors in that organ, ranging from 5 to 45 percent (Stott *et al.*, 1982).

Whereas there is evidence that TCE is carcinogenic in laboratory animals, similar evidence in humans is lacking. Several epidemiological studies have attempted to assess the association between TCE exposure in the workplace atmosphere and cancer. The Agency for Toxic Substances and Disease Registry (ATSDR, 1988b) concluded that "the available human data are inadequate to either confirm or refute the carcinogenicity of trichloroethylene" in humans via the inhalation exposure route. No studies have successfully demonstrated a significant cause and effect relationship between human cancer and ingestion of TCE-contaminated water. The International Agency for Research on Cancer (IARC, 1987) concluded that TCE cannot be classified as to its carcinogenicity in humans, based on their designation of "limited evidence" of carcinogenicity in animals and "inadequate evidence" of carcinogenicity in humans. Although EPA had listed TCE as a probable human carcinogen (B2), it withdrew this classification in 1989 and another carcinogen assessment summary is in preparation (EPA, 1996b).

Until the new summary is completed, it is assumed that TCE is a B2 carcinogen for the purposes of human health risk assessment. The previous inhalation CSF was $0.006 \text{ (mg/kg/day)}^{-1}$ and the previous oral CSF was $0.011 \text{ (mg/kg/day)}^{-1}$ (EPA, 1989). This factor is a geometric mean of four slope factors prepared by modeling the animal data on the basis of a metabolized dose. California EPA (Cal-EPA) has established an inhalation CSF of $0.010 \text{ (mg/kg/day)}^{-1}$ and has proposed an oral CSF of $0.015 \text{ (mg/kg/day)}^{-1}$. It should be noted that confidence in the carcinogenic potential of TCE in humans is low.

TETRACHLOROETHENE

COMMON SYNONYMS: <ul style="list-style-type: none">• Tetrachloroethylene• Ethylene tetrachloride	CAS NUMBER: 127-18-4 FORMULA: C ₂ Cl ₄ MOLECULAR WEIGHT: 165.83	CHEMICAL STRUCTURE
PHYSICAL/CHEMICAL DATA	Physical State - Liquid Solubility in water (mg/L) - 150 K _{oc} (mL/g) - 2.2-2.7 Diffusivity in air (cm ² /sec) - Not Available Diffusivity in water (cm ² /sec) - Not Available Henry's Law constant (atm-m ³ /mol) - 0.018 Bioconcentration factor (L/kg) - No Data	ATSDR, 1995
MAJOR USES		

INTRODUCTION

Tetrachlorethene, also known as perchloroethylene (PCE), is a widely-used solvent with applications as a dry-cleaning agent, a metal degreaser, and a chemical intermediate in the manufacturing of fluorocarbons. It is also used as a heat-exchange fluid, in the extraction of caffeine from coffee, and was formerly used as a fumigant. It is the most stable of the chlorinated ethanes and ethylenes, requiring only small amounts of stabilizers. PCE is non-flammable. Naturally-occurring sources of PCE have not been found (Bogen et al., 1987; EPA, 1996a; Torkelson and Rowe, 1981).

TOXICOKINETICS

Inhalation is the primary route of absorption into the body. PCE is readily absorbed by humans, and pulmonary uptake is proportional to ventilation rate, duration of exposure, and concentration in air. In animals, PCE is also absorbed readily and proportionally over air concentrations ranging from 10 to 600 ppm. Absorption following oral exposure of both humans and animals is rapid and virtually 100 percent. Absorption from the gastrointestinal tract has been measured in animals to be 91 to 98 percent. Absorption of PCE via the dermal route is poor in both humans and animals. Average industrial concentrations of PCE would rarely be absorbed through the human skin in toxic amounts (ATSDR, 1988a; Bogen et al., 1987; EPA, 1996a).

Distribution of PCE in the body following absorption is widespread with accumulation occurring in adipose tissue. Its metabolism is dose-dependent; at low doses a greater percentage of the absorbed dose is converted to water-soluble metabolites that are excreted in the urine. The principal metabolic pathway is oxidation. A secondary pathway involving glutathione conjugation has also been described. PCE is excreted relatively rapidly, primarily as the unchanged compound in expired air; therefore, PCE does not persist in the body (ATSDR, 1988a; Bogen et al., 1987; EPA, 1987, 1996a).

TOXICITY

Noncarcinogenic Effects

There is very little data on the toxicity of PCE in human. Acute exposure can result in irritation to lungs, eyes, and skin. In animals, the most sensitive organs and systems affected vary, depending on whether the exposure duration is acute, subchronic, or chronic, but the greatest effects appear to involve the central nervous system, liver, and kidneys. Short-term exposure tends to adversely impact the nervous system, whereas longer term exposure tends to impact the liver and kidneys. Although the reproductive system is a target, it is not as sensitive as the liver and kidneys. The toxic action of PCE is believed to be caused by reactive metabolites generated during its oxidative metabolism, which occurs primarily in the liver.

A RfD for chronic oral exposure of 0.01 mg/kg/day was calculated by EPA, using the results of a 6-week mouse gavage study (EPA, 1995). The RfD was based on hepatotoxicity (liver effects) with a NOAEL of 14 mg/kg/day and a LOAEL of 71 mg/kg/day.

Carcinogenic Effects

Whereas the evidence for carcinogenicity in rodents following inhalation exposure to PCE is considered conclusive, the evidence via oral exposure is controversial. Types of cancer observed in laboratory animals include mononuclear cell leukemia and hepatocellular (liver) and renal (kidney) carcinomas and adenomas (generally benign epithelial tumors). Humans are not susceptible to mononuclear leukemia. Evidence for a genotoxic action is weak and most studies show little to no evidence of mutagenic activity. The EPA previously classified PCE in Group B2; indicating its status as a probable human carcinogen. The B2 classification was questioned by the EPA Science Advisory Board, which has recommended a classification of Group C, indicating that it is a possible human carcinogen (EPA, 1987). The EPA is currently reconsidering the classification of PCE and has not published a classification in IRIS database.

When EPA withdraws the carcinogenic weight-of-evidence classification for a chemical published in IRIS for further review, the most recent EPA cancer slope factor is used in a risk assessment. In the case of PCE, the most recent cancer slope factor that was located is $2.0 \times 10^{-3} \text{ (mg/kg/day)}^{-1}$, established by EPA's ECAO, which has not yet been formally approved. The previously established oral slope factor of $0.052 \text{ (mg/kg/day)}^{-1}$ and inhalation slope factor of $0.002 \text{ (mg/kg/day)}^{-1}$ may also be considered appropriate (EPA, 1991).
